

# Mathematical Concepts

## Differentiation and Derivatives

- Definition of smoothness
- Uni- & multivariate differentiation
- Gradient, partial derivatives
- Jacobian matrix
- Hessian matrix
- Lipschitz continuity

# UNIVARIATE DIFFERENTIABILITY

**Definition:** A function  $f : \mathcal{S} \subseteq \mathbb{R} \rightarrow \mathbb{R}$  is said to be **differentiable** for each inner point  $x \in \mathcal{S}$  if the following limit exists:

$$f'(x) := \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}$$

Intuitively:  $f$  can be approximated locally by a lin. fun. with slope  $m = f'(x)$ .

**Left:** Function is differentiable everywhere. **Right:** Not differentiable at the red point.

# SMOOTH VS. NON-SMOOTH

- **Smoothness** of a function  $f : \mathcal{S} \rightarrow \mathbb{R}$  is measured by the number of its continuous derivatives
- $\mathcal{C}^k$  is class of  $k$ -times continuously differentiable functions ( $f \in \mathcal{C}^k$  means  $f^{(k)}$  exists and is continuous)
- In this lecture, we call  $f$  “smooth”, if at least  $f \in \mathcal{C}^1$

$f_1$  is smooth,  $f_2$  is continuous but not differentiable, and  $f_3$  is non-continuous.

# MULTIVARIATE DIFFERENTIABILITY

**Definition:** For a function  $f : \mathcal{S} \subseteq \mathbb{R}^d \rightarrow \mathbb{R}$  of  $d$  variables  $x_1, \dots, x_d$ , **partial derivatives** are defined as

$$\begin{aligned}\frac{\partial f}{\partial x_1} &= \lim_{h \rightarrow 0} \frac{f(x_1 + h, x_2, \dots, x_d) - f(\mathbf{x})}{h} \\ &\vdots \\ \frac{\partial f}{\partial x_d} &= \lim_{h \rightarrow 0} \frac{f(x_1, \dots, x_{d-1}, x_d + h) - f(\mathbf{x})}{h}\end{aligned}$$

Geometrically: Similarly to the 1D case, the vector of partial derivatives can be used to determine a tangent hyperplane. Source: [jermwatt/machine\\_learning\\_refined](#).

# GRADIENT

- Specifically, the vector of partial derivatives is called the **gradient**:

$$\nabla_{\mathbf{x}} f \text{ or } \nabla f := \left( \frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial x_2}, \dots, \frac{\partial f}{\partial x_d} \right) \quad (\text{note that this is a row vector!})$$

- This gradient of  $f$  can be used to linearly approximate  $f$ :

$$f(\mathbf{x} + \mathbf{h}) = f(\mathbf{x}) + \nabla_{\mathbf{x}} f(\mathbf{x})\mathbf{h} + o(\mathbf{h})$$

**Example:**  $f(\mathbf{x}) = x_1^2/2 + x_1 x_2 + x_2^2 \Rightarrow \nabla f(\mathbf{x}) = (x_1 + x_2, x_1 + 2x_2)$

# DIRECTIONAL DERIVATIVE

The **directional derivative** tells how fast  $f : \mathcal{S} \subseteq \mathbb{R}^d \rightarrow \mathbb{R}$  is changing w.r.t. an arbitrary direction  $\mathbf{v}$ :

$$D_{\mathbf{v}}f(\mathbf{x}) := \lim_{h \rightarrow 0} \frac{f(\mathbf{x} + h\mathbf{v}) - f(\mathbf{x})}{h} = \nabla f(\mathbf{x})\mathbf{v}$$

**Example:** The directional derivative for  $\mathbf{v} = (1, 1)$  is:

$$D_{\mathbf{v}}f(\mathbf{x}) = \nabla f(\mathbf{x}) \cdot \begin{pmatrix} 1 \\ 1 \end{pmatrix} = \frac{\partial f}{\partial x_1} + \frac{\partial f}{\partial x_2}$$

NB: Some people require that  $\|\mathbf{v}\| = 1$ . Then, we can identify  $D_{\mathbf{v}}f(\mathbf{x})$  with the instantaneous rate of change in direction  $\mathbf{v}$ , i.e.

$\lim_{h \rightarrow 0} \frac{f(\mathbf{x} + h\mathbf{v}) - f(\mathbf{x})}{h}$  – and in our example we would have to divide by  $\sqrt{2}$ .

# IMPORTANT PROPERTIES OF THE GRADIENT

- 1 **Orthogonal** to level curves/surfaces of a function
- 2 Points in direction of **greatest increase** of  $f$

# JACOBIAN MATRIX

For vector-valued function  $f : \subseteq \mathbb{R}^d \rightarrow \mathbb{R}^m$ ,  $\mathbf{x} \mapsto (f_1(\mathbf{x}), \dots, f_m(\mathbf{x}))^\top$ ,  
 $f_j : \mathcal{S} \subseteq \mathbb{R}^d \rightarrow \mathbb{R}$ , the **Jacobian** matrix  $J_f : \mathcal{S} \subseteq \mathbb{R}^d \rightarrow \mathbb{R}^{m \times d}$   
generalizes gradient by placing all  $\nabla f_j$  in its rows:

$$J_f(\mathbf{x}) \text{ or } \nabla f(\mathbf{x}) = \begin{pmatrix} \nabla f_1(\mathbf{x}) \\ \vdots \\ \nabla f_m(\mathbf{x}) \end{pmatrix} = \begin{pmatrix} \frac{\partial f_1(\mathbf{x})}{\partial x_1} & \dots & \frac{\partial f_1(\mathbf{x})}{\partial x_d} \\ \vdots & \ddots & \vdots \\ \frac{\partial f_m(\mathbf{x})}{\partial x_1} & \dots & \frac{\partial f_m(\mathbf{x})}{\partial x_d} \end{pmatrix}$$

We will mainly use the  $\nabla f$  notation.

- Jacobian gives best linear approximation of distorted volumes

# JACOBIAN DETERMINANT

Let  $f \in \mathcal{C}^1$  and  $\mathbf{x}_0 \in \mathcal{S} \subseteq \mathbb{R}^d$ .

**Inverse function theorem:** Let  $\mathbf{y}_0 = f(\mathbf{x}_0)$ . If  $\det(J_f(\mathbf{x}_0)) \neq 0$ , then

- ❶  $f$  is invertible in a neighborhood of  $\mathbf{x}_0$ ,
  - ❷  $f^{-1} \in \mathcal{C}^1$  with  $J_{f^{-1}}(\mathbf{y}_0) = J_f(\mathbf{x}_0)^{-1}$ .
- $|\det(J_f(\mathbf{x}_0))|$ : factor by which  $f$  expands/shrinks volumes near  $\mathbf{x}_0$
  - If  $\det(J_f(\mathbf{x}_0)) > 0$ ,  $f$  preserves orientation near  $\mathbf{x}_0$
  - If  $\det(J_f(\mathbf{x}_0)) < 0$ ,  $f$  reverses orientation near  $\mathbf{x}_0$

# HESSIAN MATRIX

For real-valued function  $f : \mathcal{S} \subseteq \mathbb{R}^d \rightarrow \mathbb{R}$ , the **Hessian** matrix  $\nabla^2 : \mathcal{S} \subseteq \mathbb{R}^d \rightarrow \mathbb{R}^{d \times d}$  contains all their second derivatives (if they exist):

$$\nabla^2 f(\mathbf{x}) = \left( \frac{\partial^2 f(\mathbf{x})}{\partial x_i \partial x_j} \right)_{i,j=1,\dots,d}$$

**Note:** Hessian of  $f$  is Jacobian of  $\nabla f$ . Also, the Hessian is often denoted by  $H(\mathbf{x}) \triangleq \nabla^2 f(\mathbf{x})$

**Example:** Let  $f(\mathbf{x}) = \sin(x_1) \cdot \cos(2x_2)$ . Then:

$$\nabla^2 f(\mathbf{x}) = \begin{pmatrix} -\cos(2x_2) \cdot \sin(x_1) & -2 \cos(x_1) \cdot \sin(2x_2) \\ -2 \cos(x_1) \cdot \sin(2x_2) & -4 \cos(2x_2) \cdot \sin(x_1) \end{pmatrix}$$

- If  $f \in \mathcal{C}^2$ , then  $\nabla^2 f$  is symmetric
- Many local properties (geometry, convexity, critical points) are encoded by the Hessian and its spectrum ( $\rightarrow$  later)

# LIPSCHITZ CONTINUITY

Function  $h : \mathcal{S} \subseteq \mathbb{R}^d \rightarrow \mathbb{R}^m$  is **Lipschitz continuous** if slopes are bounded:

$$\|h(\mathbf{x}) - h(\mathbf{y})\| \leq L\|\mathbf{x} - \mathbf{y}\| \quad \text{for each } \mathbf{x}, \mathbf{y} \in \mathcal{S} \subseteq \mathbb{R}^d \text{ and some } L > 0$$

- **Examples** ( $d = m = 1$ ):  $\sin(x)$ ,  $|x|$
- **Not** examples:  $1/x$  (but *locally* Lipschitz continuous),  $\sqrt{x}$
- If  $m = d$  and  $h$  **differentiable**:

$$h \text{ Lipschitz continuous with constant } L \iff J_h \preceq L \cdot \mathbf{I}_d$$

**Note:**  $\mathbf{A} \preceq \mathbf{B} : \iff \mathbf{B} - \mathbf{A}$  is positive semidefinite, i.e.,  $\mathbf{v}^T (\mathbf{B} - \mathbf{A}) \mathbf{v} \geq 0 \quad \forall \mathbf{v} \neq 0$

**Proof** of “ $\Rightarrow$ ” for  $d = m = 1$ :

$$h'(x) = \lim_{\epsilon \rightarrow 0} \frac{h(x + \epsilon) - h(x)}{\epsilon} \leq \lim_{\epsilon \rightarrow 0} \underbrace{\left| \frac{h(x + \epsilon) - h(x)}{\epsilon} \right|}_{\leq L} \leq \lim_{\epsilon \rightarrow 0} L = L$$

[**Proof** of “ $\Leftarrow$ ” by mean value theorem: Show that  $\lambda_{\max}(J_h) \leq L$ .]

# LIPSCHITZ GRADIENTS

- Let  $f \in \mathcal{C}^2$ . Since  $\nabla^2 f$  is Jacobian of  $h = \nabla f$  ( $m = d$ ):

$$\nabla f \text{ Lipschitz continuous with constant } L \iff \nabla^2 f \preceq L \cdot \mathbf{I}_d$$

- Equivalently, eigenvalues of  $\nabla^2 f$  are bounded by  $L$
- **Interpretation:** Curvature in any direction is bounded by  $L$
- Lipschitz gradients occur frequently in machine learning  
 $\implies$  Fairly **weak assumption**
- Important for analysis of **gradient descent** optimization  
 $\implies$  Descent lemma (later)
