

Optimization in Machine Learning

Second order methods

Gauss-Newton

Learning goals

- Least squares
- Gauss-Newton
- Levenberg-Marquardt

LEAST SQUARES PROBLEM

Consider the problem of minimizing a sum of squares

$$\min_{\theta} g(\theta),$$

where

$$g(\theta) = r(\theta)^\top r(\theta) = \sum_{i=1}^n r_i(\theta)^2$$

and

$$\begin{aligned} r : \mathbb{R}^d &\rightarrow \mathbb{R}^n \\ \theta &\mapsto (r_1(\theta), \dots, r_n(\theta))^\top \end{aligned}$$

maps parameters θ to residuals $r(\theta)$

LEAST SQUARES PROBLEM / 2

Risk minimization with squared loss $L(y, f(\mathbf{x})) = (y - f(\mathbf{x}))^2$

Least squares regression:

$$\mathcal{R}_{\text{emp}}(\theta) = \sum_{i=1}^n L(y^{(i)}, f(\mathbf{x}^{(i)} | \theta)) = \sum_{i=1}^n \underbrace{(y^{(i)} - f(\mathbf{x}^{(i)} | \theta))^2}_{r_i(\theta)^2}$$

- $f(\mathbf{x}^{(i)} | \theta)$ might be a function that is **nonlinear in θ**
- Residuals: $r_i = y^{(i)} - f(\mathbf{x}^{(i)} | \theta)$

Example:

$$\begin{aligned}\mathcal{D} &= \left((\mathbf{x}^{(i)}, y^{(i)}) \right)_{i=1, \dots, 5} \\ &= ((1, 3), (2, 7), (4, 12), (5, 13), (7, 20))\end{aligned}$$

LEAST SQUARES PROBLEM / 3

Suppose, we suspect an *exponential* relationship between $x \in \mathbb{R}$ and y

$$f(x | \theta) = \theta_1 \cdot \exp(\theta_2 \cdot x), \quad \theta_1, \theta_2 \in \mathbb{R}$$

Residuals:

$$r(\theta) = \begin{pmatrix} \theta_1 \exp(\theta_2 x^{(1)}) - y^{(1)} \\ \theta_1 \exp(\theta_2 x^{(2)}) - y^{(2)} \\ \theta_1 \exp(\theta_2 x^{(3)}) - y^{(3)} \\ \theta_1 \exp(\theta_2 x^{(4)}) - y^{(4)} \\ \theta_1 \exp(\theta_2 x^{(5)}) - y^{(5)} \end{pmatrix} = \begin{pmatrix} \theta_1 \exp(1\theta_2) - 3 \\ \theta_1 \exp(2\theta_2) - 7 \\ \theta_1 \exp(4\theta_2) - 12 \\ \theta_1 \exp(5\theta_2) - 13 \\ \theta_1 \exp(7\theta_2) - 20 \end{pmatrix}$$

Least squares problem:

$$\min_{\theta} g(\theta) = \min_{\theta} \sum_{i=1}^5 \left(y^{(i)} - \theta_1 \exp(\theta_2 x^{(i)}) \right)^2$$

NEWTON-RAPHSON IDEA

Approach: Calculate Newton-Raphson update direction by solving:

$$\nabla^2 g(\theta^{[t]}) \mathbf{d}^{[t]} = -\nabla g(\theta^{[t]}).$$

Gradient is calculated via chain rule

$$\nabla g(\theta) = \nabla(r(\theta)^\top r(\theta)) = 2 \cdot J_r(\theta)^\top r(\theta),$$

where $J_r(\theta)$ is Jacobian of $r(\theta)$.

In our example:

$$J_r(\theta) = \begin{pmatrix} \frac{\partial r_1(\theta)}{\partial \theta_1} & \frac{\partial r_1(\theta)}{\partial \theta_2} \\ \frac{\partial r_2(\theta)}{\partial \theta_1} & \frac{\partial r_2(\theta)}{\partial \theta_2} \\ \vdots & \vdots \\ \frac{\partial r_5(\theta)}{\partial \theta_1} & \frac{\partial r_5(\theta)}{\partial \theta_2} \end{pmatrix} = \begin{pmatrix} \exp(\theta_2 x^{(1)}) & x^{(1)} \theta_1 \exp(\theta_2 x^{(1)}) \\ \exp(\theta_2 x^{(2)}) & x^{(2)} \theta_1 \exp(\theta_2 x^{(2)}) \\ \exp(\theta_2 x^{(3)}) & x^{(3)} \theta_1 \exp(\theta_2 x^{(3)}) \\ \exp(\theta_2 x^{(4)}) & x^{(4)} \theta_1 \exp(\theta_2 x^{(4)}) \\ \exp(\theta_2 x^{(5)}) & x^{(5)} \theta_1 \exp(\theta_2 x^{(5)}) \end{pmatrix}$$

NEWTON-RAPHSON IDEA / 2

Hessian of g , $\mathbf{H}_g = (H_{jk})_{jk}$, is obtained via product rule:

$$H_{jk} = 2 \sum_{i=1}^n \left(\frac{\partial r_i}{\partial \theta_j} \frac{\partial r_i}{\partial \theta_k} + r_i \frac{\partial^2 r_i}{\partial \theta_j \partial \theta_k} \right)$$

But:

Main problem with Newton-Raphson:

Second derivatives can be computationally expensive.

GAUSS-NEWTON FOR LEAST SQUARES

Gauss-Newton approximates \mathbf{H}_g by dropping its second order part:

$$\begin{aligned} H_{jk} &= 2 \sum_{i=1}^n \left(\frac{\partial r_i}{\partial \theta_j} \frac{\partial r_i}{\partial \theta_k} + r_i \frac{\partial^2 r_i}{\partial \theta_j \partial \theta_k} \right) \\ &\approx 2 \sum_{i=1}^n \frac{\partial r_i}{\partial \theta_j} \frac{\partial r_i}{\partial \theta_k} \\ &= 2J_r(\boldsymbol{\theta})^\top J_r(\boldsymbol{\theta}) \end{aligned}$$

Note: We assume that

$$\left| \frac{\partial r_i}{\partial \theta_j} \frac{\partial r_i}{\partial \theta_k} \right| \gg \left| r_i \frac{\partial^2 r_i}{\partial \theta_j \partial \theta_k} \right|.$$

This assumption may be valid if:

- Residuals r_i are small in magnitude or
- Functions are only “mildly” nonlinear s.t. $\frac{\partial^2 r_i}{\partial \theta_j \partial \theta_k}$ is small.

GAUSS-NEWTON FOR LEAST SQUARES / 2

If $J_r(\theta)^\top J_r(\theta)$ is invertible, Gauss-Newton update direction is

$$\begin{aligned}\mathbf{d}^{[t]} &= - \left[\nabla^2 g(\theta^{[t]}) \right]^{-1} \nabla g(\theta^{[t]}) \\ &\approx - \left[J_r(\theta^{[t]})^\top J_r(\theta^{[t]}) \right]^{-1} J_r(\theta^{[t]})^\top r(\theta) \\ &= -(J_r^\top J_r)^{-1} J_r^\top r(\theta)\end{aligned}$$

Advantage:

Reduced computational complexity since no Hessian necessary.

Note: Gauss-Newton can also be derived by starting with

$$r(\theta) \approx r(\theta^{[t]}) + J_r(\theta^{[t]})^\top (\theta - \theta^{[t]}) = \tilde{r}(\theta)$$

and $\tilde{g}(\theta) = \tilde{r}(\theta)^\top \tilde{r}(\theta)$. Then, set $\nabla \tilde{g}(\theta)$ to zero.

LEVENBERG-MARQUARDT ALGORITHM

- **Problem:** Gauss-Newton may not decrease g in every iteration but may diverge, especially if starting point is far from minimum
- **Solution:** Choose step size $\alpha > 0$ s.t.

$$\mathbf{x}^{[t+1]} = \mathbf{x}^{[t]} + \alpha \mathbf{d}^{[t]}$$

decreases g (e.g., by satisfying Wolfe conditions)

- However, if α gets too small, an **alternative** method is the

Levenberg-Marquardt algorithm

$$(J_r^\top J_r + \lambda D) \mathbf{d}^{[t]} = -J_r^\top r(\theta)$$

- D is a positive diagonal matrix
- $\lambda = \lambda^{[t]} > 0$ is the *Marquardt parameter* and chosen at each step

LEVENBERG-MARQUARDT ALGORITHM / 2

- **Interpretation:** Levenberg-Marquardt *rotates* Gauss-Newton update directions towards direction of *steepest descent*

Let $D = I$ for simplicity. Then:

$$\begin{aligned}\lambda \mathbf{d}^{[t]} &= \lambda (J_r^\top J_r + \lambda I)^{-1} (-J_r^\top r(\theta)) \\ &= (I - J_r^\top J_r / \lambda + (J_r^\top J_r)^2 / \lambda^2 \mp \dots) (-J_r^\top r(\theta)) \\ &\rightarrow -J_r^\top r(\theta) = -\nabla g(\theta) / 2\end{aligned}$$

for $\lambda \rightarrow \infty$

Note: $(\mathbf{A} + \mathbf{B})^{-1} = \sum_{k=0}^{\infty} (-\mathbf{A}^{-1}\mathbf{B})^k \mathbf{A}^{-1}$ if $\|\mathbf{A}^{-1}\mathbf{B}\| < 1$

- Therefore: $\mathbf{d}^{[t]}$ approaches direction of negative gradient of g
- Often: $D = \text{diag}(J_r^\top J_r)$ to get scale invariance
(**Recall:** $J_r^\top J_r$ is positive semi-definite \Rightarrow non-negative diagonal)
