

# Optimization in Machine Learning

## First order methods: Gradient descent

### Learning goals

- Iterative Descent / Line Search
- Descent directions
- GD
- ERM with GD
- Pseudoresiduals

# ITERATIVE DESCENT

Let  $f$  be the height of a mountain depending on the geographic coordinates  $(x_1, x_2)$

$$f : \mathbb{R}^2 \rightarrow \mathbb{R}, \quad f(x_1, x_2) = y.$$

**Goal:** Reach the valley

$$\arg \min f(\mathbf{x})$$

**Central idea:** Repeat

- ① At current location  $\mathbf{x} \in \mathbb{R}^d$  search for **descent direction  $\mathbf{d}$**
- ② Move along  $\mathbf{d}$  until  $f$  sufficiently reduced (**step size control**) and update location

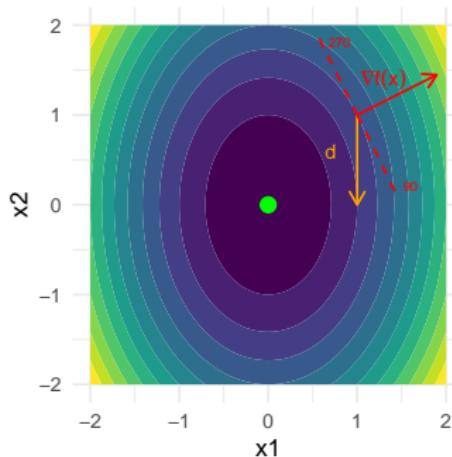

"Walking down the hill, towards the valley."

# ITERATIVE DESCENT

Let  $f : \mathbb{R}^d \rightarrow \mathbb{R}$  continuously differentiable.

**Definition:**  $\mathbf{d} \in \mathbb{R}^d / \{\mathbf{0}\}$  is a **descent direction** in  $\mathbf{x}$  if

$$D_d f(\mathbf{x}) = \nabla f(\mathbf{x})^T \mathbf{d} < 0 \text{ (neg. directional derivative)}$$

Angle between  $-\nabla f(\mathbf{x})$  and  $d$  must be  $\in (90^\circ, 270^\circ)$ .

# ITERATIVE DESCENT

---

## Algorithm 1 Iterative Descent / Line search

---

- 1: Starting point  $\mathbf{x}^{[0]} \in \mathbb{R}^d$
  - 2: **while** Stopping criterion not met **do**
  - 3:     Calculate a descent direction  $\mathbf{d}^{[t]}$  for current  $\mathbf{x}^{[t]}$
  - 4:     Find  $\alpha^{[t]}$  s.t.  $f(\mathbf{x}^{[t+1]}) < f(\mathbf{x}^{[t]})$  for  $\mathbf{x}^{[t+1]} = \mathbf{x}^{[t]} + \alpha^{[t]} \mathbf{d}^{[t]}$ .
  - 5:     Update  $\mathbf{x}^{[t+1]} = \mathbf{x}^{[t]} + \alpha^{[t]} \mathbf{d}^{[t]}$
  - 6: **end while**
- 

NB: Terminology is sometimes ambiguous: "line search" can refer to Step 4 (selecting the step size that decreases  $f(\mathbf{x})$ ) and can mean umbrella term for iterative descent algorithms.

Key questions:

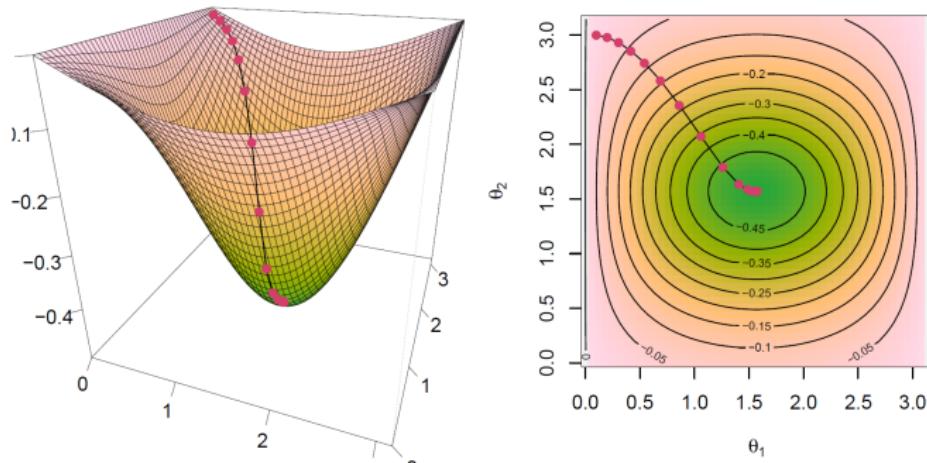

- How do choose  $\mathbf{d}^{[t]}$  (now)
- How do choose  $\alpha^{[t]}$  (later)

# GRADIENT DESCENT

Properties of gradient:

- $\nabla f(\mathbf{x})$ : direction of greatest increase
- $-\nabla f(\mathbf{x})$ : direction of greatest decrease

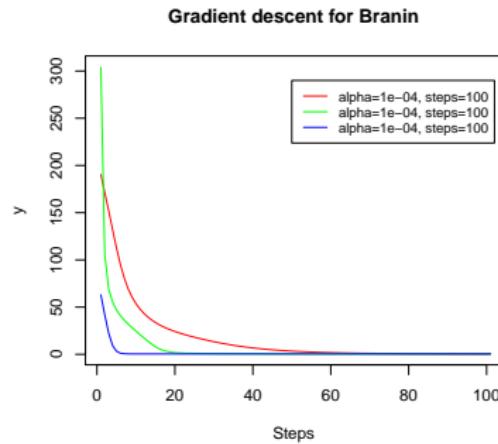

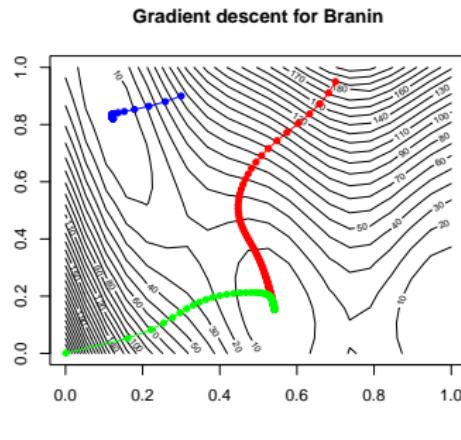

Using  $\mathbf{d} = -\nabla f(\mathbf{x})$  is called **gradient descent**.

GD for  $f(x_1, x_2) = -\sin(x_1) \cdot \frac{1}{2\pi} \exp((x_2 - \pi/2)^2)$  with sensibly chosen step size  $\alpha^{[t]}$ .

# GD AND MULTIMODAL FUNCTIONS

Outcome will depend on start point.

100 iters of GD with const  $\alpha = 10^{-4}$ .

# OPTIMIZE LS LINEAR REGRESSION WITH GD

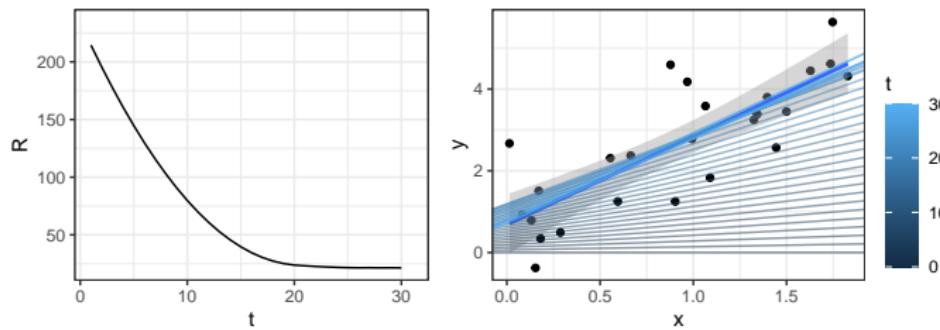

Let  $\mathcal{D} = \left( \left( \mathbf{x}^{(1)}, y^{(1)} \right), \dots, \left( \mathbf{x}^{(n)}, y^{(n)} \right) \right)$  and minimize

$$\mathcal{R}_{\text{emp}}(\boldsymbol{\theta}) = \sum_{i=1}^n \left( \boldsymbol{\theta}^\top \mathbf{x}^{(i)} - y^{(i)} \right)^2$$

**NB:** For illustration, we use GD even though closed-form solution exists. GD-like (more adv.) approaches like this MIGHT make sense for large data, though.

**Gradient:** 
$$\nabla_{\boldsymbol{\theta}} \mathcal{R}_{\text{emp}}(\boldsymbol{\theta}) = \frac{\partial \mathcal{R}_{\text{emp}}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}} = - \sum_{i=1}^n 2 \cdot \left( y^{(i)} - \boldsymbol{\theta}^\top \mathbf{x}^{(i)} \right) \mathbf{x}^{(i)}$$

# OPTIMIZE LS LINEAR REGRESSION WITH GD

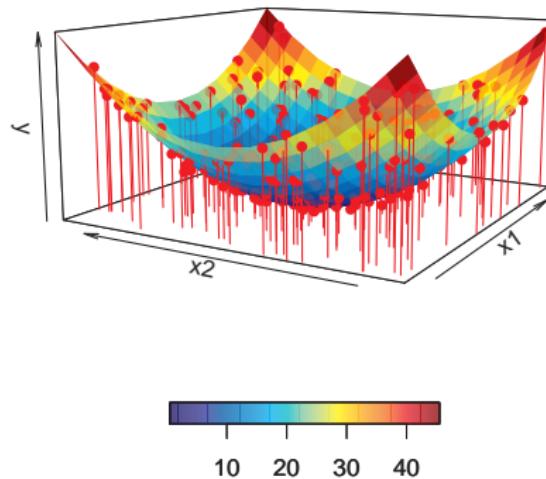

# ERM FOR NN WITH GD

Let  $\mathcal{D} = ((\mathbf{x}^{(1)}, y^{(1)}), \dots, (\mathbf{x}^{(n)}, y^{(n)}))$ , with  $y = x_1^2 + x_2^2$  and minimize

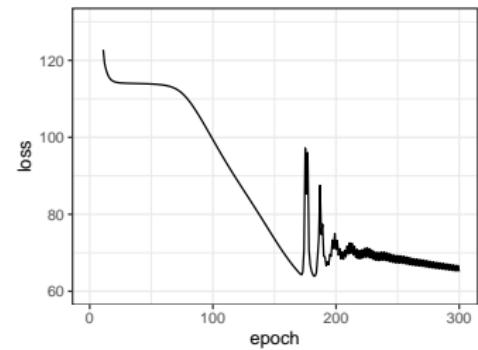

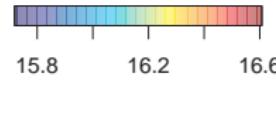

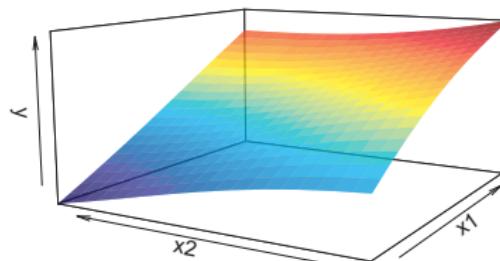

$$\mathcal{R}_{\text{emp}}(\theta) = \sum_{i=1}^n \left( f(\mathbf{x} \mid \theta) - y^{(i)} \right)^2$$

where  $f(\mathbf{x} \mid \theta)$  is a neural network with 2 hidden layers (2 units each).

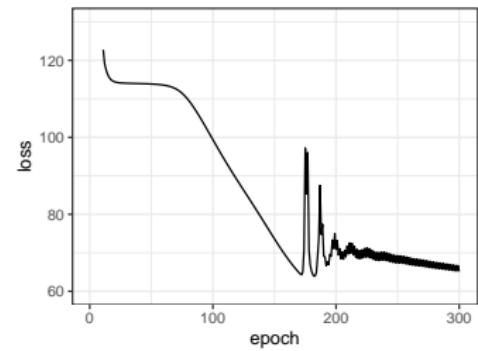

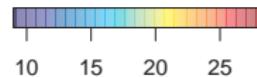

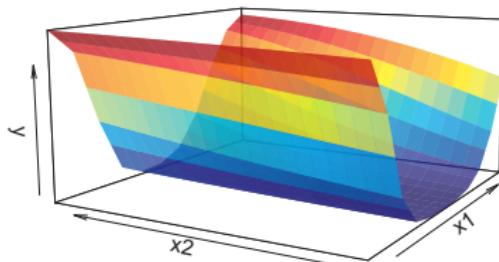

# ERM FOR NN WITH GD

After 10 iters of GD:

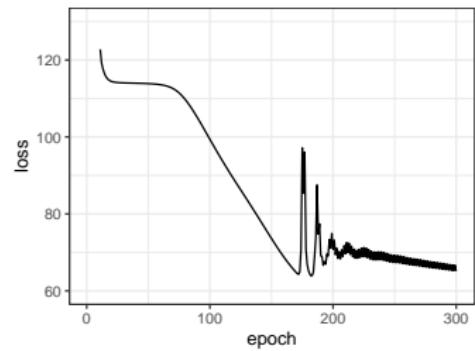

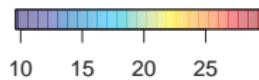

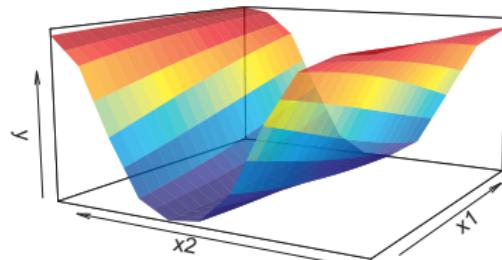

# ERM FOR NN WITH GD

After 100 iters of GD:

# ERM FOR NN WITH GD

After 300 iters of GD (note the zig-zag-behavior after iter. 200):

# GD FOR ERM: PSEUDORESIDUALS

Gradient for ERM problem:

$$-\frac{\partial \mathcal{R}_{\text{emp}}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}} = -\frac{\partial \sum_{i=1}^n L(y^{(i)}, f(\mathbf{x}^{(i)} | \boldsymbol{\theta}))}{\partial \boldsymbol{\theta}} = -\sum_{i=1}^n \underbrace{\frac{\partial L(y^{(i)}, f(\mathbf{x}^{(i)})}{\partial f(\mathbf{x}^{(i)})}}_{\text{pseudo residual } \tilde{r}^{(i)}(f)} \frac{\partial f(\mathbf{x}^{(i)} | \boldsymbol{\theta})}{\partial \boldsymbol{\theta}}$$

- **pseudo residuals** tell us how to distort  $f(\mathbf{x}^{(i)})$  to achieve greatest decrease of  $L(y^{(i)}, f(\mathbf{x}^{(i)}))$  (best pointwise update)
- $\frac{\partial f(\mathbf{x}^{(i)} | \boldsymbol{\theta})}{\partial \boldsymbol{\theta}}$  tells us how to modify  $\boldsymbol{\theta}$  accordingly and wiggle model output
- GD step sums up these modifications across all observations  $i$

**NB:** Pseudo-residuals  $\tilde{r}(f)$  match usual residuals for L2 loss:

$$\begin{aligned}-\frac{\partial L(y, f(\mathbf{x}))}{\partial f(\mathbf{x})} &= -\frac{\partial 0.5(y - f(\mathbf{x}))^2}{\partial f(\mathbf{x})} \\ &= y - f(\mathbf{x})\end{aligned}$$
